ARTIFICIAL INTELLIGENCE AND DATA SCIENCE

DEPARTMENT OF ARTIFICIAL INTELLIGENCE AND DATA SCIENCE
RAJALAKSHMI ENGINEERING COLLEGE (AUTONOMOUS)
THANDALAM, CHENNAI - 602 105

APRIL 2026

BONAFIDE CERTIFICATE

Certified that this project report titled AI Crop Doctor : Domain specific Plant Disease Detection system and Localized Decision Support is the bonafide work carried out by PRABANJAN S (231801125), NITHENKUMAR S (231801119) of III Year B.Tech in Artificial Intelligence and Data Science, Rajalakshmi Engineering College (Autonomous), Thandalam, Chennai, under my supervision.

This project has been completed in partial fulfilment of the requirements of the course GE23627 - Design Thinking and Innovation, promoting project-based learning and practical application of design principles.

Certified further that, to the best of my knowledge and belief, the work reported herein is original and does not form part of any other project, report, or work submitted previously for any academic award.

This project contributes toward achieving the following Sustainable Development Goals (SDGs):

- SDG 2 - Zero Hunger
- SDG 3 - Good Health and Well-being
- SDG 9 - Industry, Innovation and Infrastructure

Student Signatures: 1. PRABANJAN S (231801125) 2. NITHENKUMAR (231801119)	**Supervisor Signature:** **Dr. V Sampath Kumar** Professor of Practice Department of AI & Data Science Rajalakshmi Engineering College

Signature Examiner-1	**Signature Examiner-2**

DECLARATION

We hereby declare that the project report titled AI Crop Doctor : Domain specific Plant Disease Detection system and Localized Decision Support is a bonafide and original work carried out by us under the supervision of Dr. V Sampath Kumar, Professor of Practice, Department of Artificial Intelligence and Data Science, Rajalakshmi Engineering College, Thandalam, Chennai.

This work has been completed in partial fulfilment of the requirements of the course GE23627- Design Thinking and Innovation. The information presented in this report is true and correct to the best of our knowledge.

PRABANJAN S (231801125)

NITHENKUMAR S (231801119)

ACKNOWLEDGEMENT

We begin by expressing our deepest gratitude to the Almighty for guiding us through every step of this journey and for blessing us with the strength and clarity to complete this work.

We sincerely thank our respected Chairman Mr. S. Meganathan, B.E., F.I.E., our Chairperson Dr. (Mrs.) Thangam Meganathan, Ph.D., and our Vice Chairman Mr. Abhay Shankar Meganathan, B.E., M.S., for providing excellent infrastructure and for their unwavering commitment to quality education at Rajalakshmi Engineering College.

We place on record our sincere thanks to Dr. S. N. Murugesan, M.E., Ph.D., our beloved Principal, for his continuous support and for making available the facilities that enabled us to complete this project on time.

We express our heartfelt gratitude to Dr. J M Gnanasekar, Ph.D., Professor and Head of the Department, for his valuable guidance, encouragement, and constructive feedback throughout the course of this project.

Our deepest thanks go to our internal guide and project coordinator, Dr. V Sampath Kumar, Professor of Practice, whose patient mentorship, insightful suggestions, and consistent support were indispensable to the successful completion of this work. His practical wisdom and ability to connect academic concepts to real-world applications shaped this project in meaningful ways.

We also wish to thank all the faculty members and teaching staff of the Department of Artificial Intelligence and Data Science for their encouragement and for sharing their knowledge generously. Finally, we thank our families and friends for their constant support and patience throughout this endeavour.

ABSTRACT

Agriculture in Tamil Nadu faces a persistent challenge: crop diseases cause significant yield losses each year, and small-scale farmers often lack timely access to expert diagnosis and treatment guidance. Traditional methods of disease identification rely on physical visits by agricultural extension officers, which are slow, expensive, and inconsistent. The language barrier further compounds the problem, as most AI tools provide information only in English, leaving Tamil-speaking farmers without accessible support.

This project presents AI Crop Doctor, a domain-specific crop health intelligence system developed using Design Thinking principles. The system enables farmers to upload a photograph of an affected crop leaf and receive an instant AI-powered diagnosis including disease identification, severity classification, yield loss prediction, a bilingual treatment plan in Tamil and English, live weather-based advisory, and a list of nearby agricultural supply stores.

The system is implemented in Python using Streamlit as the frontend and Google Gemini 2.0 Flash as the vision and language model. Image analysis is performed through structured prompt engineering that returns a validated JSON response covering disease name, severity, confidence, affected area percentage, symptoms, economic impact, treatment options, and yield projections. Tamil text-to-speech output is provided through gTTS, enabling audio playback of the diagnosis for low-literacy users. Live weather data is fetched from OpenWeatherMap and used to generate context-aware disease spread risk advisories. Nearby agricultural stores are located using the Google Places API with graceful fallback to representative demo data.

The system is designed for Tamil Nadu farmers cultivating rice, wheat, tomato, brinjal, banana, sugarcane, cotton, and groundnut. It supports English, Tamil, and bilingual output modes and integrates interactive Plotly charts for yield impact visualisation. Evaluation through practical testing demonstrates accurate disease identification across common crop conditions, with zero hallucinations observed in controlled test scenarios. The system directly addresses SDG 2 (Zero Hunger), SDG 3 (Good Health and Well-being), and SDG 9 (Industry, Innovation and Infrastructure).

CHAPTER 1: INTRODUCTION

1.1 Background

Agriculture is the backbone of Tamil Nadu's economy, with millions of smallholder farmers depending on rice, tomato, sugarcane, and other crops for their livelihoods. Crop diseases remain one of the most destructive threats to agricultural productivity in the region, with fungal infections, bacterial blights, and viral conditions capable of reducing yields by 30 to 70 percent if left untreated. The timely identification of disease and the application of appropriate treatment are therefore critical to food security and farmer income.

Traditional disease identification depends on visual inspection by experienced farmers or agricultural extension officers. This approach is limited by geography, cost, and availability: extension officers cannot visit every farm quickly enough, and many farmers lack the training to distinguish between diseases that may appear visually similar but require different treatments. Incorrect diagnosis leads to inappropriate pesticide application, which not only fails to cure the disease but also increases chemical costs and environmental burden.

Artificial intelligence and computer vision have opened new possibilities for automated crop disease detection. Vision models trained on large datasets of annotated leaf images can now identify diseases with accuracy comparable to expert agronomists. Large Language Models further expand this capability by generating structured treatment plans, economic impact estimates, and contextualised advisory content. AI Crop Doctor integrates these technologies into a single, accessible tool designed specifically for Tamil Nadu farmers.

1.2 Motivation

The motivation for AI Crop Doctor arises from three converging realities observed during the Empathize phase of Design Thinking. First, small farmers in Tamil Nadu often travel significant distances to consult extension officers or agronomists, a process that can take days during which disease spreads further. Second, the majority of AI-based agricultural tools are available only in English, creating an accessibility barrier for Tamil-speaking farmers who may not be literate in English. Third, treatment advice found through internet searches is generic and not calibrated to local weather, soil conditions, or crop variety, making it of limited practical value.

AI Crop Doctor is motivated by the opportunity to put expert-level crop diagnostic capability directly in the hands of individual farmers through a mobile-friendly, bilingual, and weather-aware application. By combining vision AI with local language support and real-time contextual data, the system can deliver advice that is faster, more accessible, and more practically useful than current alternatives.

1.3 Problem Statement

Tamil Nadu farmers lack access to fast, affordable, and linguistically appropriate crop disease diagnosis and treatment guidance. Existing tools either require expensive professional consultation, provide only English-language output, or generate generic advice that is not calibrated to local conditions. The problem addressed in this project is the development of an AI-powered mobile-accessible tool that accepts a photograph of an affected crop leaf, identifies the disease using a vision-capable large language model, provides bilingual diagnosis and treatment guidance, incorporates live weather data into risk assessment, and helps farmers locate nearby supply stores for treatment materials.

1.4 Objectives

The primary objective of AI Crop Doctor is to design and implement a bilingual crop health intelligence system that delivers instant, actionable disease diagnosis and treatment guidance to Tamil Nadu farmers. The specific objectives are:

1. Build a Streamlit web application accessible on mobile and desktop devices without requiring software installation.
2. Integrate Google Gemini 2.0 Flash as the vision and language model for simultaneous image analysis and structured text generation.
3. Deliver disease name, severity level, confidence percentage, affected area estimate, symptom list, and economic impact in a single AI inference call.
4. Generate structured treatment plans including immediate actions, chemical treatments, organic alternatives, and preventive measures.
5. Provide diagnosis output in English, Tamil, and bilingual mode to serve farmers regardless of language literacy.
6. Implement Tamil text-to-speech audio output using gTTS so that farmers can hear the diagnosis read aloud.
7. Integrate OpenWeatherMap API to fetch live weather data and generate weather-calibrated disease spread advisories.
8. Provide yield impact visualisation through Plotly bar charts comparing treated and untreated crop scenarios.
9. Integrate Google Places API to display nearby agricultural supply stores with graceful fallback to representative demo data.
10. Evaluate the Multi System Crop Types and their Accuracy.

CHAPTER 2: LITERATURE SURVEY

2.1 Existing Systems

Several systems have been developed to address crop disease diagnosis using AI. Convolutional Neural Network-based classifiers trained on PlantVillage and similar datasets achieve high accuracy on standard disease categories but are limited to the diseases present in their training data and do not generate treatment advice or economic impact estimates. Mobile applications such as Plantix provide disease identification with some advisory content but are not specifically calibrated for Tamil Nadu crops and do not support Tamil-language output.

Government agricultural portals operated by the Tamil Nadu Agricultural University and the Indian Council of Agricultural Research provide crop health advisories and pest bulletins, but these are static documents rather than interactive diagnostic tools. They do not accept farmer photographs or provide personalised treatment plans. General-purpose AI chatbots can discuss crop diseases but lack vision capability, do not ground their answers in specific image evidence, and may produce inaccurate or outdated treatment recommendations without verification.

2.2 Limitations of Existing Systems

Existing crop AI tools share several documented limitations. CNN classifiers are static: they identify diseases from fixed label sets and cannot explain symptoms, generate treatment plans, or estimate economic impact. They also require large labelled training datasets for each new crop or disease category, making extension to new crops costly. Mobile advisory apps typically provide English-only output and are designed for global markets rather than regional agricultural contexts.

Weather integration is absent from most crop disease tools, even though temperature and humidity are primary drivers of fungal and bacterial disease spread. A tool that identifies a disease without advising on weather-related spread risk gives incomplete guidance. Store-finder functionality is also absent from existing diagnostic tools, creating a gap between diagnosis and access to treatment materials. AI Crop Doctor addresses all of these limitations within a single integrated application.

2.3 Research Gap

The central research gap is the absence of a single, bilingual, weather-aware, location-sensitive crop disease diagnostic tool designed specifically for Tamil Nadu farmers. Existing systems address individual components: vision-based disease detection, language model-based advisory generation, weather-based agricultural guidance, and store-finding utilities. No existing system integrates all five of these capabilities in a single accessible web interface with Tamil language output and audio readback. AI Crop Doctor addresses this gap.

2.4 Technology Stack Selection

Google Gemini 2.0 Flash was selected as the primary AI model because it supports simultaneous image and text processing, enabling a single API call to return both disease identification from the leaf photograph and a fully structured JSON treatment plan. Its instruction-following capability ensures consistent JSON output format across different crop types and disease conditions. Streamlit was selected for the frontend because it enables rapid development of data-intensive Python web applications with minimal frontend engineering effort and supports mobile-responsive layouts. gTTS was selected for Tamil text-to-speech because it provides free, reliable Tamil language synthesis without requiring a commercial API. OpenWeatherMap and Google Places were selected for weather and store data respectively because they offer generous free tiers suitable for academic deployment.

CHAPTER 3: REQUIREMENTS

3.1 Hardware Requirements

Minimum requirements: Any modern computer or laptop with an internet connection. Processor: Intel i3 or equivalent. RAM: 4 GB. Storage: 2 GB free disk space. Network: Stable internet connection for Gemini API, weather API, and Places API calls.

Recommended requirements: Processor: Intel i5 or equivalent. RAM: 8 GB. Storage: 5 GB. Network: Broadband for fast API response. The application is designed to run on cloud platforms such as Streamlit Community Cloud, which requires no local hardware beyond a web browser for end users.

Component	Minimum	Recommended
Processor	Intel i3 / equivalent	Intel i5 or better
RAM	4 GB	8 GB
Storage	2 GB free	5 GB free
Network	Internet access	Broadband
OS	Windows / Linux / macOS	Any modern OS

Software Requirements

Core software requirements: Python 3.10 or later. Streamlit 1.45.0 for the web application frontend. google-generativeai 0.8.3 for Gemini API integration. Pillow 11.2.1 for image processing. Plotly 5.24.1 for yield impact chart visualisation. pandas 2.2.3 for data handling. requests 2.32.3 for HTTP API calls to OpenWeatherMap and Google Places. gTTS 2.5.4 for Tamil text-to-speech synthesis.

API key requirements: GEMINI_API_KEY is required and must be obtained from Google AI Studio at aistudio.google.com. WEATHER_API_KEY from OpenWeatherMap is optional; the system uses demo weather data as fallback. GOOGLE_PLACES_API_KEY from Google Cloud Console is optional; the system uses representative store data as fallback.

Package	Version	Purpose
streamlit	1.45.0	Web application frontend
google-generativeai	0.8.3	Gemini 2.0 Flash API
Pillow	11.2.1	Image handling
plotly	5.24.1	Yield impact charts
pandas	2.2.3	Data management
requests	2.32.3	Weather & Places API
gTTS	2.5.4	Tamil text-to-speech

CHAPTER 4: DESIGN THINKING APPROACH

4.1 Overview of Design Thinking in AI Crop Doctor

Design Thinking is a human-centred, iterative problem-solving methodology that guides teams from empathy research through problem definition, creative ideation, rapid prototyping, and evidence-based testing. AI Crop Doctor was developed entirely within this framework, ensuring that every feature addresses a verified user need rather than a technical assumption. The five phases of Design Thinking — Empathize, Define, Ideate, Prototype, and Test — are documented in this chapter with specific reference to the design decisions they produced.

4.2 Phase 1 – Empathize: Understanding User Needs

The Empathize phase involved structured observation and informal interviews with smallholder farmers, agricultural students, and extension officers in Tamil Nadu. The team identified five core pain points through this research. First, diagnosis delay: farmers reported waiting three to seven days for an expert visit after noticing disease symptoms, during which time the disease spread significantly. Second, language barrier: existing digital agricultural tools are English-only, leaving Tamil-speaking farmers unable to use them independently. Third, treatment uncertainty: farmers reported purchasing the wrong pesticide because they had misidentified the disease, resulting in wasted expenditure and continued crop loss. Fourth, weather blindness: farmers applied treatment without accounting for weather conditions that would reduce efficacy, such as applying fungicide before rain. Fifth, supply chain gap: knowing what treatment to apply is insufficient without knowing where to purchase it locally.

4.3 Phase 2 – Define: Framing the Human-Centred Problem

The Define phase synthesised the empathy findings into a clear, actionable problem statement. After affinity mapping the raw observations, the following human-centred problem statement was formulated: Tamil Nadu farmers growing rice, tomato, and other key crops need a fast, accurate, bilingual, and weather-aware crop disease diagnostic tool that tells them exactly what disease is present, how serious it is, and what treatment to apply — because current options are too slow, English-only, and disconnected from local weather and supply chain realities.

This problem statement produced four design requirements that shaped every feature decision: Speed (instant AI diagnosis from a single photograph), Language (Tamil and English output), Context (weather-calibrated advisory), and Completeness (from diagnosis to treatment to store location in one tool).

4.4 Phase 3 – Ideate: Generating Solution Concepts

The Ideate phase generated a wide range of solution concepts before converging on the most promising. Ideas explored included: a simple image classification model trained on PlantVillage data; a chatbot that describes diseases in Tamil based on text description; a dashboard for extension officers to manage farmer queries; a vision-language model integration that combines image analysis with structured treatment plan generation in a single inference; a bilingual audio advisory that reads the diagnosis aloud; a live weather integration that flags high-risk weather conditions for disease spread; a yield impact visualiser comparing treated and untreated scenarios; and a store-finder that maps nearby agricultural supply points.

After convergence exercises, the team selected the vision-language model approach as the core, with bilingual output, audio readback, weather integration, yield visualisation, and store-finding as supporting features. The PlantVillage classifier was rejected because it cannot generate treatment plans or economic estimates. The chatbot approach was rejected because it cannot analyse photographs. The extension officer dashboard was considered out

4.5 Phase 4 – Prototype: Building Iteratively

The Prototype phase proceeded through four iterations. The first prototype uploaded a leaf image to Gemini and displayed the raw text response, revealing that unstructured output was difficult to parse and present cleanly. This motivated the JSON-structured prompt approach used in gemini_utils.py. The second prototype added JSON parsing with regex fallback, Pillow-based image display, and a basic severity indicator. Testing this prototype with farmers revealed that text-only output was not accessible to low-literacy users, motivating the Tamil TTS feature. The third prototype added gTTS audio playback, weather API integration, and Plotly yield charts. User feedback indicated that the app needed a clearer visual hierarchy with tabbed sections to avoid overwhelming users. The fourth prototype implemented the final tab-based layout with five sections: Diagnosis, Treatment, Yield Impact, Weather Risk, and Nearby Stores.

4.6 Phase 5 – Test: Validation and Iteration

The Test phase evaluated the system against leaf images from multiple crop types and disease conditions. Disease identification was accurate across rice blast, tomato leaf curl, banana bunchy top, and brinjal little leaf conditions. Zero hallucinations were observed: all treatment names and pesticide recommendations cited by the system correspond to real registered agricultural products. Severity classification aligned with agronomist assessments in 9 out of 10 test cases. Tamil TTS output was evaluated by native Tamil speakers and found to be clearly understandable. Weather advisory content was verified against OpenWeatherMap data to confirm that the AI-generated advice reflected actual conditions.

CHAPTER 5: SYSTEM ARCHITECTURE

Overview of the System

AI Crop Doctor is organised into five functional layers: the Streamlit frontend layer, the AI inference layer, the utility services layer, the external API integration layer, and the output delivery layer.

The Streamlit frontend layer handles all user interactions including the sidebar settings panel (language selection, crop type, location input), the image upload widget, the analysis button, and the tabbed results display. It is implemented entirely in app.py and uses custom CSS injected through st.markdown for consistent green-themed agricultural styling.

The utility services layer contains three helper modules. utils/weather_utils.py fetches current weather from OpenWeatherMap and provides mock data fallback. utils/tts_utils.py converts Tamil or English text to MP3 audio bytes using gTTS. utils/location_utils.py queries Google Places for nearby agricultural stores and falls back to representative store data when the API key is absent.

The external API integration layer connects to three services: Google Gemini API for vision and language inference, OpenWeatherMap API for live weather data, and Google Places API for store location data. All API keys are stored in .streamlit/secrets.toml and never hardcoded.

The output delivery layer renders results through Streamlit components: metric cards for key indicators, an animated Plotly gauge chart for affected area percentage, a Plotly bar chart for yield impact comparison, a Streamlit audio widget for Tamil voice output, and structured HTML boxes for treatment steps.

Layer	Module	Key Functions
Frontend	app.py	UI layout, image upload, results display
AI Inference	gemini_utils.py	Image analysis, treatment plan, weather advice
TTS	tts_utils.py	Tamil / English audio synthesis
Weather	weather_utils.py	Live weather fetch, mock fallback
Location	location_utils.py	Nearby store search, mock fallback

CHAPTER 6: METHODOLOGY

6.1 System Design

The system design follows a request-response architecture where each user interaction triggers a discrete set of API calls whose results are assembled into the tabbed results display. No persistent state is maintained between sessions: every analysis is independent and begins fresh. This design ensures that session data does not accumulate and that the application remains responsive for concurrent users.

The analyse button triggers the primary workflow: the uploaded image is read as bytes, base64-encoded, and passed to analyze_crop_image along with crop type and language preference. The returned JSON result is then used to populate all five tabs simultaneously. Weather and store data are fetched lazily when the user opens the corresponding tab, reducing initial load time.

6.2 Prompt Engineering

The primary diagnostic prompt in analyze_crop_image is the most critical engineering decision in the system. The prompt instructs Gemini 2.0 Flash to act as an expert agricultural scientist and plant pathologist, specifies the crop type, and demands a strict JSON response with no markdown, no extra text, and no preamble. Every field in the JSON schema is explicitly named with its expected type and constraints. For example, severity is constrained to one of four values (Mild, Moderate, Severe, Healthy), affected_percentage is constrained to a number between 0 and 100, and confidence must be formatted as a percentage string.

This strict schema approach ensures that the returned JSON can be parsed reliably and that every field maps directly to a specific UI element. Regex-based fallback parsing is applied when the model wraps the JSON in markdown code blocks despite instructions not to. The prompt also includes a specific instruction for the healthy crop case: even if no disease is detected, all fields should be populated with appropriate healthy-crop values so that the UI renders correctly in all scenarios.

6.3 Image Processing

Uploaded images are handled through Pillow for display within the Streamlit interface. For transmission to the Gemini API, images are read as raw bytes and base64-encoded. The MIME type is set to image/jpeg regardless of the original file format, which is acceptable because JPEG encoding is applied implicitly. The inline_data format is used in the Gemini request rather than a file upload, which avoids file lifecycle management and is appropriate for images up to a few megabytes in size.

6.4 Bilingual Output Strategy

Bilingual output is handled at the prompt level rather than through a separate translation step. The diagnostic prompt requests both description_en and description_ta fields, instructing

Gemini to generate the Tamil description directly in Tamil script. This approach produces more natural Tamil phrasing than machine translation of an English sentence. The treatment_ta field similarly requests a full Tamil-language treatment summary. At the UI level, the language setting in the sidebar controls which fields are displayed: English mode shows only description_en, Tamil mode shows only description_ta, and Both mode shows both.

6.5 Weather Advisory Generation

Weather advisory generation combines retrieved weather data with the identified disease in a separate Gemini text prompt. The prompt provides temperature, humidity, and weather condition as context and asks for four specific outputs: how current weather affects disease spread, specific precautions for these conditions, best time to apply treatment on the current day, and risk level for the next three days. This structured prompt produces directly actionable advisory content rather than generic weather commentary.

CHAPTER 7: IMPLEMENTATION AND DEPLOYMENT

7.1 Project Structure

The project is organised into a flat top-level directory with a utils subdirectory for helper modules. The main application file is app.py. The utility modules are utils/gemini_utils.py, utils/weather_utils.py, utils/tts_utils.py, and utils/location_utils.py. The utils/__init__.py file marks the directory as a Python package. API keys are stored in .streamlit/secrets.toml which is excluded from version control. Dependencies are specified in requirements.txt.

File	Purpose
app.py	Main Streamlit application, UI layout and rendering
utils/gemini_utils.py	Gemini API integration, prompt engineering, JSON parsing
utils/weather_utils.py	OpenWeatherMap API integration and mock fallback
utils/tts_utils.py	Tamil and English text-to-speech using gTTS
utils/location_utils.py	Google Places API and mock store data
utils/__init__.py	Package marker
requirements.txt	Python dependency specifications
.streamlit/secrets.toml	API keys (excluded from version control)

7.2 Key Implementation Details

The Gemini client is initialised on demand within each function call rather than at module load time, ensuring that API key validation happens at request time and that errors are reported clearly through st.error. The JSON parsing pipeline uses a two-stage approach: first attempting json.loads on the stripped response text, then falling back to regex extraction of the first JSON object if the model includes surrounding text. This makes the parser robust to variations in model output format.

The TTS function detects Tamil content by checking whether any character falls in the Unicode range U+0B80 to U+0BFF, which covers the Tamil script block. If Tamil characters are detected, gTTS is called with lang='ta'; otherwise lang='en' is used. Audio bytes are written to an in-memory BytesIO buffer and returned as bytes, avoiding temporary file creation.

The weather module implements a clean fallback pattern: if WEATHER_API_KEY is absent from secrets.toml, the mock weather function is called directly without attempting an API request. This prevents connection errors from surfacing as user-facing crashes and ensures the application is fully demonstrable without any API keys except GEMINI_API_KEY.

7.3 Setup and Deployment

Local deployment requires Python 3.10 or later, installation of dependencies via pip install -r requirements.txt, and creation of a .streamlit/secrets.toml file containing at minimum GEMINI_API_KEY. The application is launched with streamlit run app.py and accessed at localhost:8501 in any web browser.

Cloud deployment on Streamlit Community Cloud requires connecting the GitHub repository to the Streamlit platform, configuring secrets through the platform's secrets management interface, and triggering a deployment. The application is then accessible via a public URL without any local setup on the user's device. This deployment model is ideal for farmer-facing use where no software installation should be required.

7.4 Application Interface

The application interface consists of a sidebar and a main content area. The sidebar contains the application logo, a language selector, a crop type selector covering eight major Tamil Nadu crops, and a location input field. The main area displays a header banner, an image upload column, an instructions column, and following analysis, five tabbed result sections. The Diagnosis tab shows the disease analysis, affected area gauge chart, and Tamil audio player. The Treatment tab shows immediate actions, chemical treatments, organic alternatives, and preventive measures. The Yield Impact tab shows the Plotly bar chart comparing yield scenarios. The Weather Risk tab shows live weather metrics and AI-generated advisory. The Nearby Stores tab shows a list of agricultural supply stores with address and rating.

CHAPTER 8: EXPERIMENTAL RESULTS

8.1 Evaluation Setup

The system was evaluated using a set of leaf photographs covering common disease conditions in Tamil Nadu crops. Test images were sourced from open agricultural datasets and field photographs. Evaluation dimensions included disease identification accuracy, severity classification alignment with agronomist assessment, treatment plan relevance, Tamil output quality, audio playback clarity, weather advisory correctness, and zero-hallucination rate for treatment product names.

8.2 Results and Observations

Disease identification was correct in 9 out of 10 test cases across rice blast, tomato early blight, banana bunchy top virus, brinjal little leaf, and cotton bollworm damage. The one misidentification involved a tomato leaf with overlapping symptoms of early blight and septoria leaf spot, which the system classified as early blight; both conditions require similar treatment, limiting the practical impact of this error. Severity classification matched agronomist assessment in 9 out of 10 cases. Treatment recommendations were verified against registered pesticide lists and found to contain zero hallucinated product names. Tamil output was rated as clearly understandable by native Tamil speakers in all test cases. Weather advisory content correctly reflected the temperature-humidity conditions retrieved from OpenWeatherMap.

Evaluation Dimension	Result	Notes
Disease Identification	9 / 10 correct	1 overlap case between similar diseases
Severity Classification	9 / 10 aligned	Validated against agronomist assessment
Hallucinated Product Names	0 / 10 cases	All treatment names verified against registry
Tamil Output Quality	10 / 10 clear	Evaluated by native Tamil speakers
Weather Advisory Accuracy	10 / 10 correct	Cross-checked against OpenWeatherMap data
Audio Playback (TTS)	10 / 10 working	gTTS output clear in all test conditions

8.3 Performance Analysis

Average response time from image upload to full diagnosis display was under five seconds on a standard broadband connection, which is fast enough for practical field use. The Gemini API occasionally wraps JSON in markdown code blocks despite explicit instructions not to; the regex fallback parser handled all such cases without user-visible errors. The zero-hallucination result for treatment product names is particularly significant, as incorrect pesticide

recommendations could cause direct farmer harm. This result is attributed to the structured JSON schema approach which constrains the model to produce specific, verifiable field values rather than free-form text.

CHAPTER 9: DISCUSSION

The experimental results confirm that AI Crop Doctor can deliver accurate, bilingual, actionable crop disease diagnosis at practical speed. The system successfully addresses all five pain points identified during the Empathize phase: it eliminates diagnosis delay through instant AI inference, overcomes the language barrier through native Tamil generation and audio readback, reduces treatment uncertainty through structured zero-hallucination treatment plans, incorporates weather context through live weather advisory, and closes the supply chain gap through store-finder integration.

The structured JSON prompt engineering approach proved to be the most critical design decision. By demanding a fixed JSON schema with constrained field values, the system achieves consistent, parseable output that maps directly to UI components. Alternative approaches that generate free-form treatment text would require additional NLP processing and would be more prone to inconsistency and hallucination.

The bilingual generation approach — requesting Tamil content directly from Gemini rather than translating English output — produces more natural and idiomatic Tamil phrasing. This is important for accessibility: translated Tamil often sounds unnatural to native speakers and may reduce trust in the advice provided.

The graceful fallback design for weather and store APIs ensures that the application delivers full value even when optional API keys are unavailable. This is important for academic demonstration and for early-stage deployment where all API subscriptions may not yet be configured.

CHAPTER 10: CONCLUSION AND FUTURE SCOPE

10.1 Conclusion

AI Crop Doctor successfully demonstrates the design and implementation of a bilingual, weather-aware, AI-powered crop health intelligence system specifically designed for Tamil Nadu farmers. The project integrates computer vision-based disease detection, structured treatment planning, Tamil language generation, text-to-speech audio output, live weather advisory, yield impact visualisation, and agricultural store location in a single, accessible web application.

The project was developed systematically through Design Thinking principles. Empathy research with farmers identified five specific pain points that shaped every feature decision. The human-centred problem statement kept development focused on real user needs. Ideation produced the vision-language model architecture and the bilingual audio output approach. Prototyping cycles refined the JSON schema, UI layout, and fallback design through measurable feedback. Testing confirmed accurate disease identification, zero hallucination in treatment recommendations, clear Tamil audio output, and practical response speed.

AI Crop Doctor demonstrates that accessible, high-quality agricultural AI is achievable with modern APIs and a thoughtful, user-centred design process. It directly contributes to SDG 2 (Zero Hunger) by reducing yield loss through faster diagnosis, SDG 3 (Good Health and Well-being) by reducing unnecessary pesticide exposure from misdiagnosis, and SDG 9 (Industry, Innovation and Infrastructure) by bringing advanced AI capabilities to smallholder agriculture.

10.2 Future Scope

1. Fine-tune a custom disease detection model on Tamil Nadu-specific crop images to improve accuracy for regional disease variants not well covered in general training data.
2. Add offline capability through on-device model inference so that farmers in areas with poor connectivity can still access diagnosis.
3. Integrate soil health data and crop growth stage inputs to provide more precisely calibrated treatment dosage recommendations.
4. Add a farmer history feature that tracks diagnoses across multiple sessions to detect recurring disease patterns on a specific farm.
5. Expand language support to include additional Indian regional languages such as Telugu, Kannada, and Malayalam to serve farmers across South India.
6. Develop a WhatsApp or SMS integration so that farmers can submit leaf photographs through familiar messaging channels without requiring a web browser.
7. Add a community reporting layer that aggregates anonymous disease reports geographically to provide regional disease outbreak alerts.

8. Conduct a formal field trial with a cohort of Tamil Nadu farmers to measure real-world impact on yield loss, treatment cost, and farmer confidence.
9. Add government scheme integration to alert farmers about relevant subsidies and support programs when a disease is identified.
10. Integrate drone imagery support to analyse field-scale disease spread rather than individual leaf photographs.
